[updated 17 April 2020]

Abstract

The European Union is dumping its goods on world markets, especially in the UK, because the euro is a structurally undervalued currency. First, the euro is an 'incomplete' currency. Unlike every other currency, there is no single sovereign standing behind it. Each member state of the Eurozone is 'sub-sovereign', since it stands behind the euro only to a certain percentage and collectively the member states do not share joint-and-several liability. Second, the euro is an artificially 'constructed' currency, as a consequence of the fixed rates used when it was introduced in 1999 to convert the domestic currencies of EZ members into euros. This affected not only the internal exchange rates between the EZ members, but also the international value of the euro. The net result has been a downward bias in the international trading value of the euro, with the inefficient southern member states dragging down the value of the euro relative to what it would be if all member states were as efficient as Germany and the Netherlands.

The euro is undervalued against sterling on a purchasing power parity (PPP) basis by between 15.2% and 20%. As a consequence, the UK has almost always run a trade deficit with the EU over the period after the introduction of the euro. In 2018, the UK ratio of exports to imports with the EU was only 64%. While the UK maintains the close economic ties with the EU that the EU wants, the UK will remain a captive market for EZ member goods. Had the euro been correctly valued, then EZ exports to the UK in 2018 would have been lower by between £67.2bn and £88.4bn. The UK would therefore be entitled to impose an annual anti-dumping duty on the EZ in the range £67.2bn – £88.4bn.

Ursula von der Leyen says the EU is 'ready to design a new partnership with zero tariffs, zero quotas, zero dumping' with the UK. It is quite shocking that the new German president of the European Commission calls for zero dumping, when her own country is one of the world's biggest dumpers of goods onto world markets.

Key words: euro, purchasing power parity, dumping

The UK is the Eurozone's dumping ground

The EU is following a classic 'beggar thy neighbour' strategy with its trading partners, in particular the UK, by exploiting the euro's structural undervaluation

1. Introduction

The European Union (EU) is seeking a 'level playing field' with the UK after Brexit.¹ One of the key issues concerning the EU is 'dumping'. It is worried that the UK becomes a super-competitive, de-regulated 'Singapore-on-Thames' that undercuts the prices of products produced in the EU, in the same way that China does. However, the opposite is the case. It is the nineteen EU member states operating a single currency, the euro, in the Eurozone (EZ),² that are dumping their goods onto world markets – in particular the UK – because the euro is a structurally undervalued currency.

The global economic and financial community regards the euro as just another currency. However, the euro is not 'just another currency'. First, it is an 'incomplete' currency. Unlike every other currency, there is no single sovereign standing behind it. Each member state stands behind the euro only to a certain percentage³ and collectively the member states do not share joint-and-several liability. This makes them 'sub-sovereign'⁴ members of the EZ. Second, it is an artificially 'constructed' currency, as a consequence of the fixed rates used when it was introduced in 1999 to convert the domestic currencies of EZ members into euros. This affected not only the internal exchange rates between the EZ members, but also the international value of the euro.

Some member states, e.g., Italy and Spain, joined the euro at a conversion rate that turned out to be too high, given the subsequent performance of their economies. The original supporters of the euro project believed that competition would lead to this effect tapering away by virtue of what they predicted would be a productivity catch-up, but this never happened. As a result, these countries have experienced persistent structural trade deficits with some other members (for some or all of the period since the euro was introduced). Under such circumstances, normal countries could devalue their nominal exchange rate, but this option is not available to EZ members. By contrast, other member states, e.g., Germany and the Netherlands, joined the euro at a conversion rate that turned out to be too low, given the subsequent performance of their economies. These countries then experienced persistent structural trade surpluses with some other members, which would normally be eliminated by an appreciation of their 'domestic' currency – but again this is no longer possible.⁵

The net result has been a downward bias in the international trading value of the euro, with the inefficient southern member states dragging down the value of the euro relative to what it would be if all member states were as efficient as Germany and the Netherlands. This has resulted in a persistent undervaluation of the euro for the strongest economies in the EZ.

A normal sovereign stands fully behind the debts that it issues because of its power to raise taxes and because of its ability to print enough of its currency to pay back the debts in the absence of sufficient

¹ See, e.g., David Blake (2020) Ensuring a genuine level playing field with the EU post-brexite, Briefings for Britain, 28 February; <https://briefingsforbritain.co.uk/ensuring-a-genuine-level-playing-field-with-the-eu-post-brexite/>

² 19 of the 27 existing EU member states are in the Eurozone: Austria, Belgium, Cyprus, Estonia, Finland, France, Germany, Greece, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, the Netherlands, Portugal, Slovakia, Slovenia, and Spain. Denmark opted out. Bulgaria, Croatia, the Czech Republic, Hungary, Poland, Romania and Sweden are not in the Eurozone. The UK, while it was an EU member, also opted out of the euro.

³ Equal to that state's capital key in the European Central Bank: <https://www.ecb.europa.eu/ecb/orga/capital/html/index.en.html>.

⁴ A term coined by Barnabas Reynolds, David Blake, and Robert Lyddon (2020) Managing Euro Risk, Politeia, 27 February 2020.

⁵ It is important to note that, while EZ member states can no longer alter their nominal exchange rates with other member states, their real exchange rates will change when wages and prices change at a different rate from other member states.

tax raising capacity. By contrast, EZ member states, while they behave like a single sovereign state, are not jointly-and-severally liable for each other's debts, and do not have sufficient tax raising powers or the ability to print sufficient euros to pay off their total debts in full – because one country in particular, Germany, will not permit the monetisation of national debts in the EU.⁶ As a result, all EZ member states benefit from a structurally undervalued currency without 'paying' the full set of costs. This is essentially a structural form of currency manipulation, no different in principle from how some countries engage more directly in currency manipulation to lower the international value of their currency.

The euro's relative undervaluation – for the mainly northern member states – benefits EZ exporters. This, in turn, has led to persistent structural international trade surpluses being achieved by these states. However, the weakness of many mainly southern EZ economies – arising in part due to their very EZ membership – needed vast amounts of quantitative easing (QE)⁷ to ameliorate, putting further downward pressure on the euro's value.

In recent years, world attention – especially in the US – has been focused on currency undervaluation, currency manipulation, dumping and trade imbalances for one global currency, namely the Chinese renminbi (RMB).⁸ The remedies proposed have included the imposition of duties on countries that engage in these practices on the grounds that they constitute unfair trade, permitting retaliation in the form of tariffs.⁹

However, the euro has escaped this attention, including by most academic economists. One of the few papers on the topic is by Stefan Kawalec, a former vice-minister of finance of Poland. Writing in 2015, he said:¹⁰

In 2014, the Eurozone, with its huge current account surplus, was a major source of global economic imbalances. This phenomenon could last for a long time. Monetary expansion, which leads to currency depreciation, is the only macroeconomic tool available to the European Central Bank (ECB) to boost the competitiveness of struggling southern economies. With the current economic imbalances within the Eurozone, the elimination the Eurozone's current account surplus through appreciation of the euro would aggravate economic conditions in struggling member countries and could be politically explosive. Some observers hope that the Eurozone's internal imbalances can be reduced by more expansionary policies in Germany or,

⁶ Germany was behind:

- the Fiscal Stability Treaty (formally the Treaty on Stability, Coordination and Governance in the Economic and Monetary Union (TSCG)) which aims to strengthen fiscal discipline in the EZ via a balanced budget rule and an automatic correction mechanism; https://www.ecb.europa.eu/pub/pdf/other/mb201203_focus12.en.pdf;
- Article 123 of the Treaty on the Functioning of the European Union (TFEU) which prohibits any form of monetary financing of public debt or deficits;
- Article 125 of the TFEU (the 'no-bail-out clause') which precludes one member state from becoming liable for the liabilities of another member state. See Peter Praet (2012) The role of the central bank and euro area governments in times of crisis, 19 April; <https://www.ecb.europa.eu/press/key/date/2012/html/sp120419.en.html>

in the future, by wealth transfers to be enabled when the fiscal and political union materialises. Both hopes are unjustified. A huge Eurozone current account surplus is likely to persist, and this will lead to tensions with the US and other trade partners.

We will now provide evidence demonstrating the euro's structural incompleteness and undervaluation and the consequences of this for the EZ's trading partners, in particular, the UK. We will end by considering what remedies these trading partners can use to counter this undervaluation.

2. The Structural Incompleteness of the Euro

*Managing Euro Risk*¹¹ explained how the EZ's euro's structure means that member states of the EZ are not sovereign over their domestic currency and are, in effect, using a 'foreign' currency. This is because:

- since no member state individually controls the European Central Bank (ECB), EZ members are sub-sovereign, implying that the member states do not (and cannot) stand behind their government debts or currency in the way genuine sovereigns do, by printing more money to repay their debts when their tax base proves to be insufficient;
- there is no joint-and-several liability between member states or lender of last resort;
- there is no EZ-wide bank deposit insurance scheme;
- the EZ's banks are generally weak with no cross-border mergers to increase the strength of the banking system;
- as a result, the debt of member states and their public sector entities cannot be treated as sovereign quality;
- yet the EU treats this debt as of sovereign quality throughout the EU as a matter of law;
- this means the entire EZ financial system is under-capitalised, under-collateralised and with lower liquidity than required by the international standards set by the Basel Rules;¹²
- the position is made worse by the high percentage of non-performing bank loans, especially in Italy, Greece and Cyprus;
- matters are further exacerbated by a lack of transparency and bad accounting practices, leading to collateral and liquidity problems when EZ member state government bonds are used on one side of international transactions, executed through, for example, central counterparties;¹³
- as a result, the euro currency operates with vast amounts of unmanaged financial risk;
- this risk is passed into the global financial and economic system through international trading, investment and bank lending activities.

The underlying cause of this is the separation of the ECB from national member state sovereignty, meaning that no individual state can print euros independently and when euro interest rates are set, they are set by a committee in which no member state has a majority. If any one of those states finds itself in a position where it is unable to repay its debts from taxation or replacement borrowing, it

¹¹ See Barnabas Reynolds, David Blake, and Robert Lyddon (2020) *Managing Euro Risk*, Politeia, 27 February; <https://www.politeia.co.uk/managing-euro-risk-saving-investors-from-systemic-risk-by-barnabas-reynolds-david-blake-and-robert-lyddon/>

¹² Basel III: international regulatory framework for banks; <https://www.bis.org/bcbs/basel3.htm>

¹³ Also known as clearing houses.

depends on the willingness of other EZ member states to lend the money to do so – in effect by printing more euros. As a result of the structurally incomplete euro currency, with no single sovereign backer, each member state of the EZ is in effect using and financing itself in a foreign currency.

The consequence of this is that the economically stronger EZ member states use a structurally undervalued currency, gaining the full benefits of a single currency, but without the cost that any normal currency requires – which is to stand behind the currency in full in all economic and financial circumstances. In short, the euro is a currency constructed on the cheap – and the rest of the world pays the price. It also means that the risks from an under-capitalised and under-collateralised EZ financial system could be transmitted to the global markets through a domino effect, as explained in *Managing Euro Risk*. To the extent that the forex markets recognise these risks, the euro should trade at an even lower value than otherwise.

3. Economic Consequences of the Euro's Structural Incompleteness¹⁴

The Organisation for Economic Cooperation and Development (OECD) defines dumping as 'the practice by firms of selling products abroad at below costs or significantly below prices in the home market. The former implies predatory pricing; the latter, price discrimination'.¹⁵ This definition needs to be understood in the case of EZ countries as extending to 'the practice by a country of selling products abroad at artificially low prices due to the distorted international value of its currency', which in international law, as will be seen, amounts to dumping also.

In 2019, Germany had the world's largest current account surplus – which measures the net flow of goods, services and investments – at \$276bn. It was the fourth consecutive year that it held this record.¹⁶ The explanation for this is the way in which the euro and EZ were set up in 1999. Table 1 shows the weights of the 11 original constituent currencies of the euro.¹⁷

Table 1: Weights of the original 11 constituent currencies of the euro

Currency	FRF	ITL	ESP	NLG	BEF	IE£	FIM	ATS	PTE	DEM
Weight (%)	17.47	12.94	5.40	10.53	7.66	4.72	3.22	2.38	1.30	34.38

Over a third (34.38%) of the value of the euro is represented by the Deutschmark (DEM). If all 11 members were equally productive, the particular weights would not matter, because very quickly each would converge to the same structural valuation. But this has not been the case. Table 2 shows the average annual growth rate in productivity of the 11 members between 1995-2005.¹⁸ Germany had the second highest productivity growth rate at 1.9%, while Italy and Spain had the lowest at 0.5% and 0.0%, respectively.

¹⁴ I am grateful to Professor Kevin Dowd, Professor Patrick Minford and Lord Peter Lilley for their comments on this section. The usual caveat applies.

¹⁸ Labour productivity is defined as real value added per working hour. Source: Table 1 of Steffen Elstner, Lars P. Feld, and Christoph M. Schmidt (2018) *The German Productivity Paradox – Facts and Explanations*, Ruhr Economic Papers #767, RWI – Leibniz-Institut für Wirtschaftsforschung, Essen, Germany, 2018: ISSN 1864-4872; http://www.rwi-essen.de/media/content/pages/publikationen/ruhr-economic-papers/rep_18_767.pdf.

Table 2: Average annual growth rate in productivity of the original 11 Eurozone members, 1995-2005

Country	FRA	ITA	ESP	NLD	BEL	IRL	FIN	AUT	PT	DEU
Productivity growth (%pa)	1.8	0.5	0.0	1.7	NA	NA	2.6	1.8	NA	1.9

This has two important implications. The first is that with fixed nominal exchange rates, EZ member states with a lower productivity level – which is typically measured by real per capita gross domestic product (GDP) – will find themselves at a competitive disadvantage when it comes to intra-EZ trade – and one that grows systematically over time. The second is that the low productivity EZ member states will help to pull down the value of the euro on the international currency markets compared with the DEM. In other words, the introduction of the euro has completely distorted the market in traded goods and services (1) between EZ member states themselves and (2) between the EZ and the rest of the world (ROW). Germany – and to a lesser extent the Netherlands – has been the biggest beneficiary of both these distortions. Notwithstanding the high quality of German goods, this is equivalent to dumping its artificially low-priced goods on the markets of both other EU states and the ROW, especially the UK post-Brexit, which until Brexit was a convenient captive market because EU law required the UK to accept the EZ's structure and disregard any unfairness that arose as a consequence.

3.1 The distortions caused by the euro between EZ member states

Figure 1 shows how the undervaluation of the euro compared with the DEM and Dutch Guilder has benefitted Germany and the Netherlands in terms of intra-EU exports.¹⁹ The two countries have 23% and 11%, respectively, of intra-EU exports. This compares with 21% and 4.9%, respectively, of EU GDP.^{20,21} The Netherlands' share of intra-EU exports is larger than that of France, Italy and Spain which constitute 14.1%, 11.1% and 7.6%, respectively, of EU GDP.

Figure 1: Exports of goods to other member states, 2018 (% of total intra-EU exports)

¹⁹ https://ec.europa.eu/eurostat/statistics-explained/index.php?title=Intra-EU_trade_in_goods_-_main_features&oldid=452727.

²⁰ EU GDP, 2018. Source: Eurostat; <http://appsso.eurostat.ec.europa.eu/nui/submitViewTableAction.do>; <http://appsso.eurostat.ec.europa.eu/nui/setupDownloads.do>. Note, that the Netherlands estimate of the share of intra-EU exports might be upward biased due to the Rotterdam effect: goods from EU member states exported via the port of Rotterdam will be recorded as Dutch exports. Also note that in 2018, the German share of intra-EU exports was only 2 percentage points above its share of EU GDP. It might be expected to be higher, given the German productivity growth rate in Table 2. However, Germany has, like many other developed countries, experienced a fall in productivity growth in recent years, as explained in Steffen Elstner, Lars P. Feld, and Christoph M. Schmidt (op cit), which has had the effect of bringing down the German share of intra-EU exports.

²¹ Also note the high UK share of intra-EU exports. This, of course, is swamped by the size of intra-EU imports. For example, in 2018, the UK exported £291bn of goods and services to the EU, but imported £357bn (<https://researchbriefings.files.parliament.uk/documents/CBP-7851/CBP-7851.pdf>).

Figure 2 shows Germany's trade surplus between November 1990 and November 2019.²² During this period, Germany has always run a trade surplus, except briefly around the time of reunification. What is striking is the significant increase in the surplus since the introduction of the euro in 1999. This can be explained, in part, by Germany joining the euro at a very favourable conversion rate for the DEM.²³ With floating exchange rates, countries with trade surpluses normally experience an increase in their nominal exchange rate which helps to reduce the surplus. This cannot happen in a fixed exchange rate regime like the EZ. Of course, the size of Germany's trade surplus will help to drive up the relative international value of the euro, but by no means as much as the DEM would have risen in the same circumstances.

Figure 2: Germany's trade balance with the rest of the world between November 1990 and November 2019

Figure 3 shows the Netherlands' trade surplus between January 1996 and November 2019.²⁴ There is a similar pattern as in the case of Germany, although it is more volatile. The explanation is the same.

Figure 3: The Netherlands' trade balance with the rest of the world between January 1996 and November 2019

²² <https://www.ceicdata.com/en/indicator/germany/trade-balance>.
²³ We provide additional explanations for Germany's trade surplus below.
²⁴ <https://www.ceicdata.com/en/indicator/netherlands/trade-balance>.

Figure 4 shows Italy's trade balance between January 1993 and November 2019.²⁵ Prior to joining the euro in 1999, Italy had a trade surplus. But between 1999 and 2012, it mostly ran a trade deficit. This was because Italy joined the euro at an uncompetitively high conversion rate against the lira, leading to a fall in its exports relative to its imports. The reduction in exports was sufficient to lower the Italian growth rate to zero – and it has remained close to zero ever since. In other words, the Italian economy has barely grown in the last 20 years. This, in turn, explains why there was a trade surplus after 2012. The economy was so depressed that imports fell by more than exports to such an extent that a trade surplus returned. But the reason for the trade surplus in Italy's case is very different from that explaining Germany's surplus. In Italy's case, it is mainly the result of weak domestic demand for imported goods. In Germany's case, it is the result of strong international demand for its exports.

Figure 4: Italy's trade balance with the rest of the world between January 1993 and November 2019

Figure 5 shows Spain's trade balance between January 1990 and November 2019.²⁶ Unlike Italy, Spain has always had a trade deficit. Nevertheless, once we control for this, the experiences of the two Mediterranean economies have been very similar after they joined the euro. The Spain's trade deficit worsened considerably after joining the euro before recovering to pre-euro levels following the 2007-08 financial crisis. The reason is the same as in the case of Italy. Spain joined the euro at too high a conversion rate against the peseta. This reduced exports which, in turn reduced economic growth, via a negative multiplier effect. The financial crisis was followed by the Great Recession of 2008-12 which reduced the demand for imports and perversely improved the trade deficit. The same effect is there as in Figure 4 for Italy.

²⁵ <https://www.ceicdata.com/en/indicator/italy/trade-balance>.

²⁶ <https://www.ceicdata.com/en/indicator/spain/trade-balance>.

Figure 5: Spain trade balance with the rest of the world between January 1990 and November 2019

Figure 6 shows the TARGET2²⁷ balances for EZ member states between November 2001 and November 2019.²⁸ In November 2019, Germany's credit balance was €840bn, while the debit balances for Italy and Spain were €428bn and €373bn, respectively. This is a direct consequence of the trade distortions caused by having a fixed exchange rate in the EZ, together with capital flight from Italy and Spain to Germany following the financial crisis.

TARGET2 was established to process cross-border payments within the EZ. These payments are ultimately for private-sector end-users, be they financial institutions, corporates or individuals. TARGET2 has the effect of converting private-sector cross-border liabilities into sovereign cross-border liabilities of EZ member states which are then treated by EU law as risk-free. To illustrate, suppose an Italian company imports machinery from a German company and finances this with a loan from its Italian bank. The Italian bank debits the loan account and makes a payment into the German company's German bank. This, in turn, leads to a TARGET2 debit for the Banca d'Italia and a TARGET2 credit for the Bundesbank. The balances between the Banca d'Italia and the Bundesbank are not settled, but are rather novated to the ECB at end-of-day, before being reversed back on to their original accounts at the start of the following day. The Banca d'Italia would retain either a deposit of the Bundesbank on its books or an overdraft on its own account at the Bundesbank. Either way, the private Italian company's loan has become a liability of the Italian government to the German government – and hence becomes part of Italy's national debt.²⁹

²⁷ TARGET2 is the high-value real-time gross settlement payment system for the euro, comprising the national high-value payment systems of the 19 Eurozone member states, the euro-denominated high-value payment systems in five non-Eurozone EU member states, and the arrangements between TARGET2-participating central banks and the ECB to make cross-border payments. All business in euros contracted with Eurosystem members must be settled through TARGET2, and it also carries the main financial markets business between financial institutions, as well as the settlements of balances in other Financial Markets Infrastructures.

²⁸ <http://www.eurocrisismonitor.com/>.

²⁹ TARGET2 has become a mechanism for bailing out the euro. Eurozone member states are able to borrow through the TARGET2 system without paying interest and without having to repay the loan. This should be regarded as a form of subsidy, mainly from Germany, to compensate for the euro's incomplete structure. See David Blake (2018) Target2: The Silent Bailout System that Keeps the Euro Afloat, SSRN, 22 May; https://papers.ssrn.com/sol3/papers.cfm?abstract_id=3182995.

Figure 6: TARGET2 balances for Eurozone member states, November 2001- November 2019

Figure 6 shows that the system was broadly in balance between the launch of the euro and the financial crisis. The Great Recession that followed – which was much worse in Italy and Spain than in Germany – led to a loss of confidence in the Italian and Spanish banking sectors and investors and depositors moved their funds to German, Luxembourg, and Dutch banks through TARGET2. This is clearly visible in the Figure. Also visible is the effect of the European Sovereign Debt Crisis which peaked between 2010 and 2012.³⁰ It began in 2008 with the collapse of Iceland's banking industry and then spread to Portugal, Italy, Ireland, Greece, and Spain in 2009. The governments in these EZ countries had to borrow heavily to bail out their banks. Yields on the government bonds rose and the markets closed on them to further borrowing. Fearing financial contagion and the collapse of the euro, the EU and the IMF provided the necessary loans. But the capital flight from Italy and Spain during the period is transparent.

3.2 The distortions caused by the euro between the EZ and the rest of the world

The euro is undervalued internationally on a purchasing power parity (PPP) basis, and has been for most of the time since it was introduced – although not by as much as the RMB. The OECD defines purchasing power parities by reference to the rates of currency conversion that equalise the purchasing power of different currencies, by eliminating the differences in price levels between countries. The basket of goods and services priced is a sample of all those that are part of final expenditures: final consumption of households and government, fixed capital formation, and net exports.

³⁰ <https://www.investopedia.com/terms/e/european-sovereign-debt-crisis.asp>.

Table 3: Ratio of purchasing power parity to actual exchange rates for selected countries, 1999-2019

Year	Eurozone	UK	Japan	Canada	China
1999	0.932	1.174	1.423	0.802	0.327
2000	0.797	1.066	1.436	0.826	0.327
2001	0.770	1.000	1.232	0.788	0.326
2002	0.806	1.034	1.147	0.783	0.323
2003	0.971	1.137	1.203	0.875	0.326

2005	1.061	1.287	1.175	1.002	0.345
2006	1.039	1.283	1.071	1.063	0.358
2007	1.125	1.421	1.022	1.129	0.393
2008	1.186	1.290	1.130	1.157	0.455
2009	1.108	1.105	1.231	1.052	0.459
2010	1.050	1.084	1.272	1.186	0.489
2011	1.086	1.131	1.346	1.253	0.543
2012	0.995	1.108	1.307	1.245	0.558
2013	1.003	1.087	1.038	1.188	0.570
2014	0.999	1.149	0.973	1.114	0.569
2015	0.838	1.058	0.855	0.976	0.556
2016	0.808	0.930	0.970	0.910	0.521
2017	0.811	0.878	0.939	0.928	0.522
2018	0.845	0.917	0.947	0.925	0.537
2019	0.800	0.880	0.948	0.906	0.512
Average	0.957	1.109	1.138	1.003	0.445
<p>Note: Exchange rates are measured in terms of national currency units per US dollar.</p> <p>Source: OECD (2019), Purchasing power parities (PPP) (indicator). doi: 10.1787/1290ee5a-en</p> <p>PPP rates: https://data.oecd.org/conversion/purchasing-power-parities-ppp.htm#indicator-chart</p> <p>Actual rates: https://data.oecd.org/conversion/exchange-rates.htm#indicator-chart</p>					

Table 3 shows the ratio of PPP to actual exchange rates in the EZ, the UK, Japan, Canada and China between 1999 and 2019. Figure 7 shows a graph of this ratio for the EZ, the UK and China over the same period. Since nominal exchange rates are measured in terms of national currency units per US dollar, a ratio below unity indicates undervaluation of the actual currency relative to its PPP value. To illustrate, in 1999, the ratio was 0.932 in the EZ: this is found by taking the ratio of the PPP exchange rate in 1999 (0.874) to the actual exchange rate in the same year (0.938). This means that, absent transactions costs, it would be possible to buy a good in the EZ for €0.874, sell it in the US for \$1, exchange the proceeds back into euros at the actual exchange rate of 0.938, and make a profit of 6.8% (i.e., 1 minus 0.932, the ratio of the PPP and actual exchange rates). There would be no profit if the actual exchange rate equalled its PPP value of 0.874. The Table shows that, except for the period around the Global Financial Crisis, the euro has been undervalued on a PPP basis, by an average of

4.3%. Sterling and the Japanese yen, by contrast, were overvalued over the period by an average of 10.9% and 13.8%, respectively.³¹ Sterling has been undervalued on a PPP basis only since 2016, and that is due to the market's overreaction to the Brexit Referendum result. Not surprisingly, given its geographical proximity to the US, the Canadian dollar has traded on average at its PPP value over the period. Only the RMB has traded at a lower value on a PPP-adjusted basis than the euro, averaging 0.445 – an undervaluation of 55%. Figure 7 shows that the undervaluation of the euro is the greatest it has ever been except for 2001. The Figure shows quite clearly why the US is concerned about the RMB. But what is surprising is why there has been no comparable outcry over the euro. This provides very powerful support for the argument made above that the way that the euro was structured and valued at inception has allowed the euro to remain undervalued ever since.

Figure 7: Ratio of purchasing power parity to actual exchange rates for the Eurozone, the UK and China, 1999-2019

The euro's relative undervaluation is increased by virtue of EZ member states avoiding the full costs of operating a single currency. The EU is a single trading area – a customs union – under WTO rules. The 27 member states of the EU are accorded this recognition because they have a common internal trading area – the single market – and a common external tariff schedule. Within that trading area, some states have individual currencies, in the normal way. There is also the EZ with 19 members of the EU that use a single currency, the euro. However, as discussed above, the EZ comprises sub-sovereign states with no sovereign state sitting above them. This arrangement gives those states the economic benefits of a structurally undervalued currency, whilst they avoid the costs of joint-and-several liability that is both intrinsic to a proper currency zone and a key feature of the sovereign entity that sits at the top of a genuinely federal collection of states. This set-up cannot have been envisioned to be legitimate under WTO rules which were conceived before the euro existed, since it is a structural lacuna which has resulted in a persistent trade advantage.³²

³¹ The main reason for sterling's overvaluation lies in capital account activities. There is a high demand for sterling coming from (1) foreign direct investors, including portfolio and real estate investors, buying UK equities, government bonds and property (there are few other politically stable countries that allow such unrestricted access) and (2) the repatriation of dividends, etc, from the UK's relatively large holding of overseas investments, in particular, by institutional investors, such as pension funds. See, e.g., Ashoka Mody (2016) Don't believe what you've read: the plummeting pound sterling is good news for Britain, Independent, 10 October; <https://www.independent.co.uk/news/business/comment/why-the-plummeting-pound-sterling-is-good-news-for-britain-a7353846.html>

Michael Burrage and Phil Radford (2020) WTO vs the EU: an assessment of the UK's trade relationships 1999-2018, Civitas, forthcoming.

UK goods exports to the 14 leading countries that the UK trades with on WTO terms (denoted WTO14) – meaning in the absence of a preferential trade agreement – had a CAGR of 3.58%,³⁵ compared with 0.62% for the EZ12. So they grew nearly six times faster between 1999 and 2018 than trade with the EZ12, despite the higher tariffs.

One explanation frequently offered for why the UK's trade with the ROW has grown at a faster rate than its trade with the EU and, in particular, EZ countries is that the ROW's economies have grown at a faster rate over the last 20 years. The aggregate CAGR of the GDP of the WTO14 was 3.53% between 1999 and 2018.³⁶ This is indeed significantly higher than the 1.44% GDP CAGR of the EZ12.³⁷

However, Column 2 of Table 5 shows the CAGRs of UK exports to the EZ12 compared with the CAGR of their GDP. The growth of UK goods exports to the EZ12 over these two decades was below the

³⁴ Had we assumed that the present 27 EU members had all been single market members over the same period, the CAGR of UK goods exports to all 27 would have been slightly higher at 0.78%.

³⁵ Table 2 of Michael Burrage and Phil Radford (2020) WTO vs the EU: an assessment of the UK's trade relationships 1999-2018, Civitas, forthcoming.

³⁶ <https://data.worldbank.org/indicator/NY.GDP.MKTP.KD> 2010.

³⁷ And also higher than the 1.73% growth rate of the EU27.

growth of the GDP of them all, except for the Netherlands.³⁸ Something more than the differential growth rates in the economies of these two groups of countries must be involved. It cannot be related to the quality of the goods offered for sale or indeed the UK's marketing abilities within the EU single market – since neither has impeded UK export growth outside the EZ. A key explanation must lie in the euro and its systematic undervaluation compared with sterling – which makes UK exports to the EZ look expensive.

Table 3 shows that the average undervaluation of the euro against the US dollar over the period 1999-2019 was 4.3% (1 minus 0.957), while the average overvaluation of sterling against the US dollar was 10.9% (1.109 minus 1). This means that the euro was undervalued against sterling by 15.2% (4.3 plus 10.9). If we disregard the period after 2016 when sterling fell as a market overreaction to the Brexit Referendum, then sterling was overvalued against the US dollar over the period 1999-2015 by 15.7%, and hence the euro's undervaluation against sterling was 20%.

Table 6 shows that the UK mostly had a trade surplus with the countries outside the EU. This is reinforced by the trade figures for 2019. Last year, UK exports to non-EU countries increased by 13.6% over 2018 to £201.5bn, while UK exports to the EU fell by 0.9% to £170.6bn, accounting for just 45.8% of the total.³⁹ We trade on WTO terms with some key non-EU countries, including the US (the UK's biggest single trading partner), China (the UK's third biggest trading partner after Germany), Japan, Canada, Australia, India and Brazil. Despite this, our trade grew at a faster rate than with the EU where trade is supposed to be 'frictionless'. Further, Table 6 shows that the UK mostly had a trade surplus with non-EU countries during 1999-2018.⁴⁰

In 2018, the UK ratio of exports to imports with the EU27 was only 64%.⁴¹ Figure 9 shows the UK goods trade deficit with EU member states in 2018.⁴² Particularly noteworthy is the scale of the deficit with Germany, mainly in automobiles. Even allowing for potential quality differences between British and German cars, a key explanation for the size of this deficit is again the undervaluation of the euro. While the UK maintains the close economic ties with the EU27 that the EU wants, the UK will remain a captive market for German and other EZ member goods and will be unable to address the structural disadvantage which it finds itself in. Figure 10 shows the much smaller UK services trade surplus with EU member states in 2018.⁴³

We can conclude that the increase in the total UK trade deficit in Figure 8 is due almost exclusively to the increase in the trade deficit with the EZ and that this is, in turn, due to the persistent undervaluation of the euro. This has allowed EZ member states – and especially Germany and the Netherlands – to dump their products onto the UK market. The EZ is also able to dump onto global markets for the same reason.

This problem is recognised in Germany, although not as a problem of dumping. For example, Gabriel Felbermayr, the director of the Munich-based ifo Center for International Economics has recently said:⁴⁴

Germany exporting more than it imports is becoming a big problem for its economy. [The trade surplus] is turning out to be an increasing issue, not just with the U.S. but with other trade partners as well, and also within the European Union. The surplus is becoming toxic, and also

³⁸ This could be explained by the Rotterdam effect.

within Germany many argue now that we need to do something about it with the purpose of lowering it. It turns out to be a liability rather than an asset.

Germany's export-orientated, manufacturing economy and its resulting trade surplus – the value of its exports exceeding that of its imports – has long been a subject of criticism and Berlin has been pressured to encourage more domestic spending and boost imports. Trade surpluses are viewed as encouraging trade protectionism and worsening the economic problems of other countries.

Table 6: UK trade with non-EU countries (goods and services), 1999-2018

3.4 Explanations for the euro's persistent undervaluation

We have provided evidence above that the euro has been undervalued against sterling, in particular, on a PPP basis for the whole of its existence – see Figure 7.

However, many economists would argue that within a common currency area, like the EZ, prices and wages should eventually equalise, removing internal trade imbalances, and, in an open global macroeconomy context, PPP should hold in the long run, i.e., there should be a long-run equilibrium in relative EZ prices to ROW prices (measured in a common currency), which should remove the relative undervaluation of the euro and, in turn, remove external trade imbalances in due course.

Nevertheless, persistent deviations of exchange rates from PPP levels have been noted by academic economists for some time. Early studies include Frenkel (1976), Kravis, Heston and Summers (1982) and Kravis and Lipsey (1978, 1982, 1987, 1988).⁴⁵ Kravis, Heston and Summers (1982), for example, found that prices levels in some developing countries were one third of the US price level, so our estimate of the euro's undervaluation against sterling of between 15.2% and 20% is not out of line with historical evidence.

Kravis and Lipsey (1978) were amongst the earliest economists to suggest that long-term deviations from PPP implied that the exchange rate market is in disequilibrium. Economists tend not to like the idea that an economic system can be in a state of disequilibrium – at least on a permanent basis. This gave rise to a debate, essentially between Keynesians and monetarists, which, in turn, generated

⁴⁵ Jacob A. Frenkel (1976) A monetary approach to the exchange rate: Doctrinal aspects and empirical evidence, *Scandinavian Journal of Economics*, 78(2), 200-224;
Irving B. Kravis, Alan W. Heston, and Robert Summers (1982) *World Product and Income*, Baltimore: Johns Hopkins University Press;
Irving B. Kravis and Robert E. Lipsey (1978) Price behavior in the light of balance of payments theories, *Journal of International Economics*, 8(2), 193-246;
Irving B. Kravis and Robert E. Lipsey (1982) *Toward an Explanation of National Price Levels*, Princeton Studies in International Finance No. 52, Princeton, NJ: International Finance Center, Princeton University;
Irving B. Kravis and Robert E. Lipsey (1987) The assessment of national price levels, in Sven W. Arndt and J. David Richardson (eds) *Real Financial Linkages Among Open Economies*, Cambridge, MA: MIT Press, 97-134;
Irving B. Kravis and Robert E. Lipsey (1988) National price levels and the prices of tradeables and non-tradeables, *American Economic Review*, May 1988 (Papers and Proceedings), 78, 474-8.

'disequilibrium' and 'equilibrium' models of the exchange rate. On the one hand, economists like Dornbusch (1976, 1987)⁴⁶ developed a disequilibrium model that could explain short-run deviations from PPP but moved towards PPP in the long-run – which is not consistent with the facts. On the other hand, economists like Lucas (1978)⁴⁷ and Stockman (1987)⁴⁸ developed equilibrium models that allow for permanent departures from PPP, but do not explain short-run exchange rate dynamics.

So the economic literature is not clear on whether there can be long-run deviations from PPP, nor is it clear on how long it should take for a disequilibrium in the foreign exchange market to disappear. The evidence in Table 3 above shows that the undervaluation of the euro against sterling on a PPP basis has persisted for the two decades that the euro has existed. Further, there are two reasons to suppose that the undervaluation of the euro will persist for some time.

First, the euro is undervalued because it is a structurally incomplete currency, as explained in *Managing Euro Risk*. But even introducing measures that reduced this incompleteness – joint-and-several liability between member states, a lender of last resort, a EZ-wide bank deposit insurance scheme, etc – would be insufficient to remove the undervaluation in full. Only when the EZ members form themselves into a fully federal state, with political and fiscal union – and associated fiscal transfers from richer to poorer regions – can we expect to see the euro's undervaluation on account of its structural incompleteness disappear. The cause of the euro's undervaluation, in this case, is political not economic. The benefits of this lacuna go to the northern EZ states with internal and external trade surpluses, while the costs and risks are borne by the southern EZ states and the ROW.

Second, there is an economic reason explaining the euro's persistent undervaluation that is not related to a disequilibrium in the foreign exchange market. Kravis and Lipsey (1983, 1987, 1988) found that most cross-country deviations from PPP could be explained by differences in per capita real GDP, i.e., by differences in productivity. This finding is confirmed for European countries by Berka and Devereux (2010).⁴⁹ They show that 'there are large and persistent deviations from absolute PPP among all European countries. ...The deviations have not been eliminated by membership of the single currency area. Even among Eurozone members, there are persistent departures from PPP that show no obvious signs of erosion within the sample'. Particularly significant is the finding that 'real exchange rates are very closely tied to relative GDP per capita, both in comparisons across countries, and in movement over time, at all levels of aggregation. The data show that some countries displayed declining relative GDP per capita over time, combined with persistent depreciation in their real exchange rate – in particular, this applied to the "Old-Europe" countries; France, Germany, the Netherlands, Belgium, and Austria, while other countries displayed substantial appreciation combined with increasing relative GDP per capita – notably Ireland, the UK, some Scandinavian countries, as well as many countries of emerging Eastern Europe'. Further, 'a one percent increase in the relative GDP per capita for a given country towards the European average leads to a 0.35 to 0.40 percent appreciation of the real exchange rate to the European average'.

These findings are consistent with the Balassa-Samuelson model,⁵⁰ which uses productivity differences to explain systematic differences in prices and wages between countries, as well as systematic differences between national incomes (expressed in a common currency) and their PPP values. The model predicts that if real exchange rate differentials are driven primarily by differences in income per capita (i.e., productivity), countries with GDP per capita equal to the EU average should have real exchange rates at the EU average (i.e., PPP should hold). Countries with lower (higher) than average relative GDP should have lower (higher) real exchange rates. Further, for a country that begins with a

⁴⁶ Rudiger Dornbusch (1976) Expectations and exchange rate dynamics, *Journal of Political Economy*, 84, 1161-74;

Rudiger Dornbusch (1987) Exchange rates and prices, *American Economic Review*, 77(1), 93-106.

⁴⁷ Robert E. Lucas (1978) Asset prices in an exchange economy, *Econometrica*, 46(6), 1429-45.

⁴⁸ Alan C. Stockman (1978) The equilibrium approach to exchange rates, *Federal Reserve Bank of Richmond Economic Review*, March/April, 12-30.

⁴⁹ Martin Berka and Michael B. Devereux (2010) What determines European real exchange rates?, Working Paper, Massey University and University of British Columbia, 16 July.

⁵⁰ Bela Balassa (1964) The purchasing power parity doctrine: A reappraisal, *Journal of Political Economy*, 72, 584-596;

Paul A. Samuelson (1964) Theoretical notes on trade problems, *Review of Economics and Statistics*, 46, 145-154.

GDP per capita below the average, relative GDP per capita should be below the real exchange rate. But if the country catches up and overtakes the average, its relative GDP per capita should cross the real exchange rate from below and converge to a position where relative GDP per capita is above the real exchange rate. The opposite should hold for a country with falling relative GDP per capita.

This is broadly what Berka and Devereux (op. cit.) find over their data period (1995-2007):

- Real exchange rates are positively correlated with real per capita GDP. Over the data period, Belgium, Germany, France, Austria and the Netherlands all have GDP per capita close to the EU average, and the same holds for their real exchange rates. For Greece, Spain, Portugal and (for most of the period) Italy, real exchange rates and relative GDPs per capita were considerably below the EU average, while the Scandinavian countries and (for most of the period) the UK, both real GDP per capita and real exchange rates were substantially above the EU average.
- Movements in relative GDP per capita tend to be associated with movements in real exchange rates in the same direction. This is particularly true for the floating exchange rate countries, i.e., Sweden, UK, Iceland, Norway and Switzerland.
- Once a country joins the euro, its nominal exchange rate relative to other EZ members cannot change, but its real exchange rate can change if nominal prices are slow to adjust. Germany, France, Austria and to a lesser extent Belgium and the Netherlands experienced substantial real exchange rate depreciation after joining the EZ, while Ireland, Italy, Spain and Portugal went through real exchange rate appreciation.

Figure 11 provides some more recent information which covers the full period of the euro's existence up to 2018.⁵¹ Particularly striking is the observation that over the period, UK and German real per capita GDP both grew by a total of around 30%, but, while real per capita personal disposable income (PDI) grew by the same amount in the UK, it grew by only 19% in Germany. In other words, German wages have been held down very severely compared with those in the UK. The situation has been even worse in the Netherlands, Spain, Belgium and, especially Italy, where real PDI has fallen by 6% since the euro was introduced.

How is this possible? There are a number of explanations.

First, in Germany, there was the 2003 labour market and welfare reform package – known as Agenda 2010 – introduced by chancellor Gerhard Schröder. Designed to reduce unemployment from 11.6% and kickstart the German economy, the reforms included: cuts in welfare benefits, reducing the amount of time unemployment benefits could be drawn, making it easier to hire and fire workers, allowing more part-time and temporary work, and tax breaks to workers and corporations.⁵² These reforms reduced unemployment, but also the growth in real wages.

Second, high unemployment rates have depressed real wage growth in the EZ. Across the EZ, the unemployment rate is 7.5%. It is 16.6% in Greece, 13.9% in Spain, 9.7% in Italy, 8.6% in France, and 7.7% in Cyprus. This compares with 2.5% in Switzerland, 2.2% in Japan, 3.5% in the US and 3.8% in the UK. Within the EZ, only the Netherlands at 3.2% and Germany at 3.1% have comparable low figures – the latter case showing the success of the Schröder reforms in reducing unemployment.⁵³ The rate of youth unemployment is considerably worse. It is 15.6% across the Eurozone. It is 35.6% in Greece, 32.1% in Spain, 28.6% in Italy, 18.9% in France, and 17.2% in Cyprus. This compares with 2.4% in Switzerland, 3.8% in Japan, 8.1% in the US and 11.4% in the UK. Even Netherlands at 6.7% and Germany at 5.9% have a significant problem with youth unemployment.⁵⁴

A third explanation lies in EU directives and European Court of Justice (ECJ) rulings which favour employers' rights over workers' rights and help to suppress wages in the EU.⁵⁵ Three examples will demonstrate this.

Employees in one member state are prevented from picketing or striking in protest against the use of imported cheaper workers. This follows from the Laval and Viking cases in 2007. In the former case, the Swedish building workers union was found to have acted unlawfully when it picketed a construction company that was employing Latvian workers who were paid 40% less. The latter case involved Estonian workers undercutting Finnish workers. In the Ruffert case in 2008, the German state of Lower Saxony contracted a company to build a prison on the condition that it paid workers the collectively-agreed minimum wage for the sector. But the company brought in workers from Poland and paid them 54% less. Lower Saxony tried to cancel the contract, but the ECJ ruled that this restricted the company's right to provide cross-border services. As another German example, in 2005, Volkswagen told the workers at its Wolfsburg factories that it would move production to Poland unless they accepted a three-hour increase in the working week without any increase in pay (effectively an 8% pay cut). The unions had no alternative but to agree to the demand.

Figure 11: Real per capita growth in GDP and PDI (after-tax personal disposable income) in selected European countries, 1998-2018

Figure 11 shows the consequences of these explanations for incomes across the whole EZ. The effect of the directives and rulings, in particular, has allowed EZ companies to use cheap labour in the EZ (both directly and to produce cheap components) to make finished products that undercut the prices of products in international markets. Part of the explanation for the improved trade balance in Italy and Spain after 2012 (Figures 4 and 5) is the sale of cheap components to other EZ states such as Germany; these components are cheap because as Figure 11 shows they are made by workers whose real wages have been severely constrained for the last 20 years. This is in addition to the competitive advantage

⁵⁵ As explained in David Blake (2019) The Single Market isn't working – why doesn't the Left understand this?, Briefings for Brexit, 2 November; <https://briefingsforbritain.co.uk/the-single-market-isnt-working-why-doesnt-the-left-understand-this/>

from an undervalued euro. Producers in countries like the UK therefore face a double whammy from EZ imports which are being dumped onto the UK market – where dumping is being used in both the original OECD definition and our proposed additional definition.

Following Brexit, UK producers could face a third whammy in the form of rules of origin (ROO). EU products are made predominantly using inputs acquired from within the EU, not imported from abroad. They thereby benefit from ROO requirements which specify high levels of local components, reducing any the negative impact that a structurally low euro value has on raising the cost of imported components. This reinforces the explanation as to why EZ products are cheap when they are sold abroad. British products by contrast are disadvantaged because a much higher percentage of raw materials have to be imported. To illustrate, only 25% of the parts in a UK built car are purchased in the UK, the rest are imported. Accordingly, the UK may suffer from tight ROO requirements for cars in a future free trade agreement (FTA) with a partner such as the US which tends to require high threshold ROO, perhaps exceeding 55%.

4. Potential Remedies under International Law⁵⁶

The structurally undervalued euro potentially violates two areas of international law: dumping and subsidies.

First, Article VI of the General Agreement on Tariffs and Trade (GATT) points out that multiple currency practices can 'constitute a form of dumping by means of a partial depreciation of a country's currency', thereby benefitting EZ exporters unfairly. The anti-dumping remedy in this case is the imposition by the importing state of an additional duty on the dumped goods. One method of determining the size of the additional tariff would be the World Trade Organisation (WTO)'s Anti-Dumping Agreement (ADA) using the surrogate price method.⁵⁷

Second, artificially low currencies could amount to an export subsidy and therefore breach the WTO's Agreement on Subsidies and Countervailing Measures (SCM).^{58,59} The US Department of Commerce has announced that it intends to impose countervailing duties on products which benefit from unfair currency subsidies.⁶⁰ In addition, southern EZ countries are indirectly subsidising cheap German and other northern state exports, not only by producing cheap components made by workers on falling real wages, but also dragging down the international value of the euro relative to the DEM.

The evidence needed to establish that a subsidy exists is outlined in Article 1 of the SCM which specifies that a subsidy exists if:

- (a) there is a financial contribution by a government or any public body;
- (b) a benefit is thereby conferred; and

⁵⁶ I am grateful to Professor David Collins and Barney Reynolds for discussions on this section. The usual caveat applies. For a fuller analysis of the ideas in this section, see David Collins (2020) *How to Level the EU's Playing Field: Trade Remedies for a Trade Deal*, Politeia.

⁵⁷ The normal value of the product is assessed by reference to what it is in a third country which is not a currency manipulator.

⁵⁸ E.g., A. de Lima-Campos and J. A. Gaviria (2012), A Case for Misaligned Currencies as Countervailable Subsidies, 46 *Journal of World Trade*, 46, 1017, and B. B. Caryl (2011), Is China Currency Regime a Countervailable Subsidy? A Legal Analysis Under the World Trade Organization's SCM Agreement, *Journal of World Trade*, 45, 187-219.

⁵⁹ Daniel Stelter argues that the euro is a 'subsidy for our export-oriented industries which we finance ourselves by giving credit to our international customers, even though most of the latter will never be in a position to pay this credit back', quoted in Will Italy Spell the End of the Euro?, *The Globalist*, 22 May 2018; <https://www.theglobalist.com/italy-elections-eurozone-ecb-economy/>

⁶⁰ US Department of Commerce (2020), Department of Commerce Issues Final Rule for Countervailing Unfair Currency Subsidies, 4 February; <https://www.commerce.gov/news/press-releases/2020/02/departments-commerce-issues-final-rule-countervailing-unfair-currency>.

(c) the subsidy is specific to an enterprise or industry or group of enterprises.

There is a question mark over whether an undervalued euro would meet the 'specificity' requirement, since the whole economy benefits rather than a specific enterprise or industry. However, some have argued that an undervalued exchange rate constitutes an export subsidy with the remedy under WTO rules being countervailing measures to offset the extent of the subsidy.⁶¹

Our PPP evidence provides a useful way of calculating the size of the anti-dumping or countervailing duty, avoiding any difficulties associated with estimating surrogate prices. The data in Table 3 shows that on a PPP basis, the euro was undervalued against sterling by between 15.2% and 20%. Given that EZ exports to the UK were £303.9bn in 2018,⁶² and given the UK has an import price elasticity of -1.455,⁶³ this means that, had the euro been correctly valued, EZ exports to the UK in 2018 would have been lower by between £67.2bn⁶⁴ and £88.4bn.⁶⁵ The UK would therefore be entitled to impose an annual anti-dumping or countervailing duty on the EZ in the range £67.2bn - £88.4bn (based on 2018 export figures).

5. Conclusion

We have provided powerful economic evidence that the euro is persistently structurally undervalued and that as a consequence, the EZ, in general, and Germany and the Netherlands, in particular, are dumping goods at below fair market values onto world markets, in general, and the UK, in particular. We estimate that the euro is undervalued against sterling by between 15.2% and 20%, and that had the euro been correctly valued, then EZ exports to the UK in 2018 would have been lower by between £67.2bn and £88.4bn. The UK would therefore be entitled to impose an annual anti-dumping or countervailing duty on the EZ in the range £67.2bn - £88.4bn. The euro also acts as a subsidy to firms from within these countries, giving them an advantage over global competitors. The subsidy is reinforced by EU directives and ECJ rulings which have driven down real wages in the richer parts of the EU in the presence of intense competition from low-wage workers in the poorer parts of the EU.

The EU is following a classic 'beggar thy neighbour'⁶⁶ strategy. This is where a country or trading bloc follows a protectionist trade strategy that adversely affects its trading partners. Typically, this involves tools such as tariffs and quotas. But in this case, the weapon is a structurally undervalued currency.

The UK government is introducing a Trade Bill which will establish a new Trade Remedies Authority to prevent countries from dumping cheap goods onto the UK market, potentially putting key domestic industries, like steel, out of business. The Trade Remedies Authority will enable the UK to conduct its own dumping and subsidies investigations. The Bill may have been intended to target China in particular,⁶⁷ but trade remedies can be levied against any WTO member, including the EU, whether or not there is an FTA in place.

We have made two striking findings. The first is that we have been able to quantify the degree of euro undervaluation against sterling, at between 15.2% and 20%. The second comes from the study by Michael Burrage and Phil Radford which showed that over the period of the euro's existence, UK exports to the rest of the world grew approximately six times faster than UK exports to the Eurozone –

proving conclusively that our falling relative share of trade with the EZ is primarily caused by an undervalued euro. These findings were not the result of sophisticated economic modelling, rather they are obvious from a straightforward examination of publicly available data from the OECD and the UK Office for National Statistics. These findings ought to be well known, not only in the UK, but also in the EU and beyond. But they are not.

Instead, we are told that the EU 'holds all the cards' in the upcoming trade negotiations with the UK. European Commission President Ursula von der Leyen says the EU is 'ready to design a new partnership with zero tariffs, zero quotas, zero dumping' with the UK.⁶⁸ The EU's current treaty-based proposal for avoiding trade dumping would involve the UK applying EU law, including, extraordinarily (and uniquely in international trade between properly sovereign nations) the application of that law as interpreted by the European Court of Justice. This would, of course, have the effect of permanently advantaging Germany and other EZ member state beneficiaries of the EZ's structural lacuna to the detriment of the UK, continuing an arrangement that is demonstrably unfair to the UK.

It is quite shocking that the new German president of the European Commission calls for zero dumping, when her own country is one of the world's biggest dumpers of goods onto world markets. Equally shocking is the deafening silence of influential organisations in the UK, like the Treasury, the Bank of England, the Confederation of British Industry, and especially the BBC, which has enabled the myth that the EU holds all the cards to be perpetuated for so long. This must come to an end.
